

Create a Power Automate flow that triggers on every new message sent by a specific sender in a Microsoft Teams chat. Parse messages containing 4-column tabular data and save the extracted information in a timestamped Excel file on the D drive. For every new message, compare its data against the previously saved Excel file: append only non-duplicate records to the old file, and reply in Teams listing any records already present (duplicates). The flow should use Teams "new chat message" triggers, sender filtering, robust data parsing, deduplication logic, and update/send feedback to the chat automatically. All steps and actions must be handled reliably for seamless end-to-end automation.
